## ABSTRACT:

PROBLEM TO BE SOLVED: To improve the flatness of an integrated circuit by hydrogen-treating a heat resistant metal oxide deposited by using a hydrogen plasma or hot hydrogen, and altering non-electric conductivity of the treated metal oxide to electric conductivity.

SOLUTION: A heat resistant metal oxide layer hydrogen-treated by using a hydrogen plasma or hot hydrogen and exposed is converted into a conductive layer. Heat resistant metal oxide layers 116b1 116b2 exposed by the hydrogen-treatment are converted into conductive layers. Meanwhile, non-exposed heat resistant metal oxide layer 116a is still retained in a state of a non-conductive layer. A second conductive layer is formed on the metal oxide layer, and then patterned. As a result an upper surface of an upper electrode 118a of a capacitor 120 and first and second contact mutual connectors 121, 122 become the same relative heights. Thus, the smoothness (flatness) of the integrated circuit can be improved.

## ABSTRACT:

PROBLEM TO BE SOLVED: To prevent putting on an epitaxial layer caused during cleaning by controlling metal fine particle not attached directly to the layer.

SOLUTION: The epitaxial wafer EPW obtained at the step S2 is taken out from the reaction chamber at the step S3 and then immediately contacted with the air containing ozone at the S4 to form the chemical silicon oxidation membrane on the surface of the epitaxial layer E. Even when the metal fine particle is attached during a certain measurement and inspection at the step 5 and the step 6, the chemical silicon oxidation membrane controls oxidation- reduction reaction between the silicon epitaxial layer E and the metal fine particle M, leading not to the strong attachment of the particle. Thanks to this, pit is not caused at the silicon epitaxial layer E even after SC1 cleaning and SC2 cleaning at the step S7.

## ABSTRACT:

PURPOSE: To obtain high-purity products and to lessen the consumption of an apparatus by stabilizing the temp. of waste piranha acid in a charging section, then lowering a pressure in a distillation system to refine sulfuric acid and transferring the waste to a removing system.

CONSTITUTION: The piranha acid used in washing, etching, etc., of semiconductors is introduced from a charging line 1 into a prepn. device (charging section) 2 where the temp. is stabilized. The piranha acid is then discharged gradually to the product distillation system 3. The pressure is lowered and the temp. is elevated in the treatment process. The refined sulfuric acid (product) is transferred into an accepting tank 8 or is recirculated to a junction point 11. The waste acid, heavy metal contaminant and particulates (sludge) are transferred from the product distillation system 3 to a waste removing system 4 and are discharged to a waste collecting tank 9. A coolant system 5 is used for changing the temp. of the coolant of the cooler of the distillation system 3. Feed water cools the heat exchanger of the waste removing system 4.
